Data Information

Ge the data from: http://www.nyc.gov/html/tlc/html/about/trip_record_data.shtml (2016 data) The data used in the attached datasets were collected and provided to the NYC Taxi and Limousine Commission (TLC)

Information on taxis:

Yellow Taxi: Yellow Medallion Taxicabs

These are the famous NYC yellow taxis that provide transportation exclusively through street-hails. The number of taxicabs is limited by a finite number of medallions issued by the TLC. You access this mode of transportation by standing in the street and hailing an available taxi with your hand. The pickups are not pre-arranged.

For Hire Vehicles (FHVs)

FHV transportation is accessed by a pre-arrangement with a dispatcher or limo company. These FHVs are not permitted to pick up passengers via street hails, as those rides are not considered pre-arranged.

Green Taxi: Street Hail Livery (SHL)

The SHL program will allow livery vehicle owners to license and outfit their vehicles with green borough taxi branding, meters, credit card machines, and ultimately the right to accept street hails in addition to pre-arranged rides.

Credits: Quora

Footnote:

In the given notebook we are considering only the yellow taxis for the time period between Jan - Mar 2015 & Jan - Mar 2016

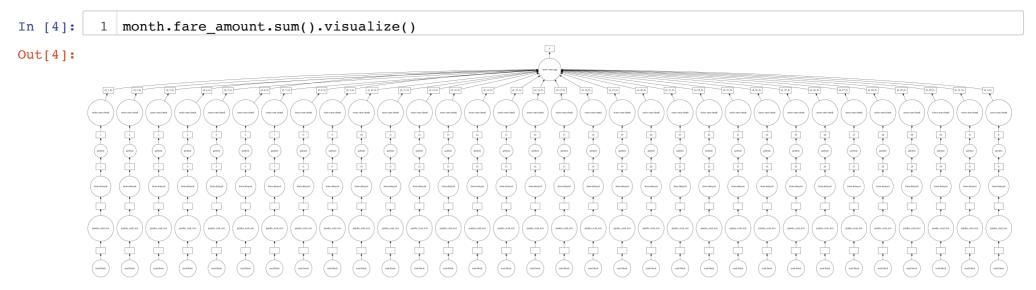

Data Collection

We Have collected all yellow taxi trips data from jan-2015 to dec-2016(Will be using only 2015 data)

In [3]:
         1 # However unlike Pandas, operations on dask.dataframes don't trigger immediate computation,
           # instead they add key-value pairs to an underlying Dask graph. Recall that in the diagram below,
            # circles are operations and rectangles are results.
           # to see the visulaization you need to install graphviz
            # pip3 install graphviz if this doesnt work please check the install graphviz.jpg in the drive
           month.visualize()
Out[3]:
```

Features in the dataset:

```
Dropoff longitude
  Longitude where the meter was disengaged.
Dropoff latitude
  Latitude where the meter was disengaged.
Payment_type
  A numeric code signifying how the passenger paid for the trip.
  Credit card 
     Cash 
     No charge 
     Dispute
     Unknown 
     Voided trip
  Fare_amount
  The time-and-distance fare calculated by the meter.
Extra
  Miscellaneous extras and surcharges. Currently, this only includes. the $0.50 and $1 rush hour
and overnight charges.
MTA tax
  0.50 MTA tax that is automatically triggered based on the metered rate in use.
Improvement surcharge
```

```
<0.30 improvement surcharge assessed trips at the flag drop. the improvement surcharge began bei
ng levied in 2015.
Tip amount
   Tip amount - This field is automatically populated for credit card tips. Cash tips are not inclu
ded.
Tolls amount
   Total amount of all tolls paid in trip.
Total amount
   The total amount charged to passengers. Does not include cash tips.
```

Description		Field Name
A code indicating the TPEP provider that provided the record. Creative Mobile Technologies VeriFone Inc.	1. 2.	VendorID
The date and time when the meter was engaged.		tpep_pickup_datetime
The date and time when the meter was disengaged.		tpep_dropoff_datetime
The number of passengers in the vehicle. This is a driver-entered value.		Passenger_count
The elapsed trip distance in miles reported by the taximeter.		Trip_distance
Longitude where the meter was engaged.		Pickup_longitude
Latitude where the meter was engaged.		Pickup_latitude
The final rate code in effect at the end of the trip. Standard rate JFK Newark Nassau or Westchester Negotiated fare Group ride	1. 2. 3. 4. 5.	RateCodeID

This flag indicates whether the trip record was held in vehicle memory before sending to the vendor, store_and_fwd_flag

Store_and_fwd_flag

This flag indicates whether the trip record was held in vehicle memory before sending to the vendor, aka "store and forward," because the vehicle did not have a connection to the server.

Y= store and forward trip

N= not a store and forward trip

ML Problem Formulation

Time-series forecasting and Regression

- To find number of pickups, given location cordinates(latitude and longitude) and time, in the query reigion and surrounding regions.

To solve the above we would be using data collected in Jan - Mar 2015 to predict the pickups in Jan - Mar 2016.

Performance metrics

- 1. Mean Absolute percentage error.
- 2. Mean Squared error.

Data Cleaning

In this section we will be doing univariate analysis and removing outlier/illegitimate values which may be caused due to some error

In [5]:

- 1 #table below shows few datapoints along with all our features
- 2 month.head(5)

Out[5]:

	VendorID	tpep_pickup_datetime	tpep_dropoff_datetime	passenger_count	trip_distance	pickup_longitude	pickup_latitude	RateCodeID	store_and_f

1. Pickup Latitude and Pickup Longitude

It is inferred from the source https://www.flickr.com/places/info/2459115) that New York is bounded by the location cordinates(lat,long) - (40.5774, -74.15) & (40.9176,-73.7004) so hence any cordinates not within these cordinates are not considered by us as we are only concerned with pickups which originate within New York.

```
1 # Plotting pickup cordinates which are outside the bounding box of New-York
In [6]:
            # we will collect all the points outside the bounding box of newyork city to outlier locations
            outlier locations = month[((month.pickup longitude <= -74.15) | (month.pickup latitude <= 40.5774) |
                                (month.pickup longitude \geq -73.7004) | (month.pickup latitude \geq 40.9176))
         5
            # creating a map with the a base location
            # read more about the folium here: http://folium.readthedocs.io/en/latest/quickstart.html
          8
            # note: you dont need to remember any of these, you dont need indeepth knowledge on these maps and plots
        10
        11
            map osm = folium.Map(location=[40.734695, -73.990372], tiles='Stamen Toner')
        12
            # we will spot only first 100 outliers on the map, plotting all the outliers will take more time
        13
            sample locations = outlier locations.head(10000)
            for i, j in sample locations.iterrows():
        15
                if int(j['pickup latitude']) != 0:
        16
                    folium.Marker(list((j['pickup latitude'],j['pickup longitude']))).add to(map osm)
        17
        18
            map osm
```

Observation:- As you can see above that there are some points just outside the boundary but there are a few that are in either South america, Mexico or Canada

2. Dropoff Latitude & Dropoff Longitude

It is inferred from the source https://www.flickr.com/places/info/2459115) that New York is bounded by the location cordinates(lat,long) - (40.5774, -74.15) & (40.9176,-73.7004) so hence any cordinates not within these cordinates are not considered by us as we are only concerned with dropoffs which are within New York.

```
# Plotting dropoff cordinates which are outside the bounding box of New-York
In [7]:
            # we will collect all the points outside the bounding box of newyork city to outlier locations
            outlier locations = month[((month.dropoff longitude <= -74.15) | (month.dropoff latitude <= 40.5774) |
                               (month.dropoff longitude >= -73.7004) | (month.dropoff latitude >= 40.9176))]
          5
            # creating a map with the a base location
            # read more about the folium here: http://folium.readthedocs.io/en/latest/quickstart.html
          8
            # note: you dont need to remember any of these, you dont need indeepth knowledge on these maps and plots
        10
            map osm = folium.Map(location=[40.734695, -73.990372], tiles='Stamen Toner')
        11
        12
            # we will spot only first 100 outliers on the map, plotting all the outliers will take more time
        13
            sample locations = outlier locations.head(10000)
            for i, j in sample locations.iterrows():
        15
                if int(j['pickup latitude']) != 0:
        16
                    folium.Marker(list((j['dropoff latitude'],j['dropoff longitude']))).add to(map osm)
        17
        18
            map osm
```

Observation:- The observations here are similar to those obtained while analysing pickup latitude and longitude

3. Trip Durations:

According to NYC Taxi & Limousine Commision Regulations the maximum allowed trip duration in a 24 hour interval is 12 hours.

```
1 #The timestamps are converted to unix so as to get duration(trip-time) & speed also pickup-times in unix ar
In [8]:
         2
           # in out data we have time in the formate "YYYY-MM-DD HH:MM:SS" we convert thiss sting to python time forma
           # https://stackoverflow.com/a/27914405
           def convert to unix(s):
         6
                return time.mktime(datetime.datetime.strptime(s, "%Y-%m-%d %H:%M:%S").timetuple())
         7
         8
         9
        10 # we return a data frame which contains the columns
        11 # 1. 'passenger count' : self explanatory
        12 # 2. 'trip distance' : self explanatory
        13 # 3. 'pickup longitude' : self explanatory

```

Inference:

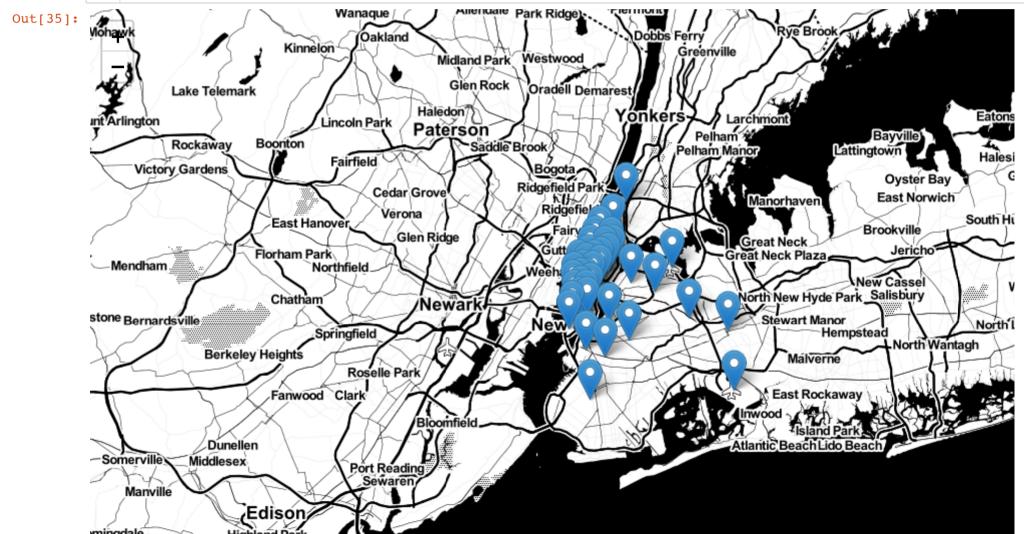

• The main objective was to find a optimal min. distance(Which roughly estimates to the radius of a cluster) between the clusters which we got was 40

```
In [34]:

# if check for the 50 clusters you can observe that there are two clusters with only 0.3 miles apart from end 2 # so we choose 40 clusters for solve the further problem

# Getting 40 clusters using the kmeans
kmeans = MiniBatchKMeans(n_clusters=40, batch_size=10000,random_state=0).fit(coords)
frame_with_durations_outliers_removed['pickup_cluster'] = kmeans.predict(frame_with_durations_outliers_removed)
```

Plotting the cluster centers:

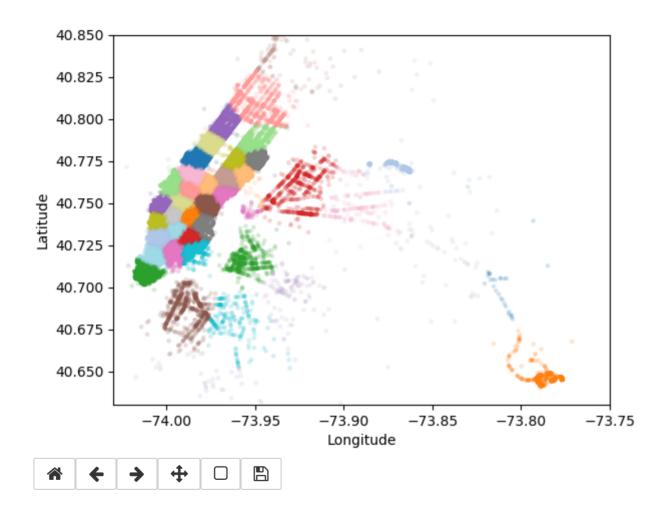

Leaflet (https://leafletjs.com) | Mar thes by Stam Design (http://openstreetmap.org), under ODOL (http://www.spens.com)

Plotting the clusters:

```
In [36]:
          1 #Visualising the clusters on a map
          2 def plot clusters(frame):
                 city long border = (-74.03, -73.75)
           3
                 city lat border = (40.63, 40.85)
                 fig, ax = plt.subplots(ncols=1, nrows=1)
           5
                 ax.scatter(frame.pickup longitude.values[:100000], frame.pickup latitude.values[:100000], s=10, lw=0,
           6
           7
                            c=frame.pickup cluster.values[:100000], cmap='tab20', alpha=0.2)
                 ax.set xlim(city long border)
           8
           9
                 ax.set ylim(city lat border)

Modelling: Baseline Models

Now we get into modelling in order to forecast the pickup densities for the months of Jan, Feb and March of 2016 for which we are using multiple models with two variations

- 1. Using Ratios of the 2016 data to the 2015 data i.e $R_t = P_t^{2016}/P_t^{2015}$
- 2. Using Previous known values of the 2016 data itself to predict the future values

Simple Moving Averages

The First Model used is the Moving Averages Model which uses the previous n values in order to predict the next value

Using Ratio Values - $R_t = (R_{t-1} + R_{t-2} + R_{t-3} \dots R_{t-n})/n$

```
def MA R Predictions(ratios, month):
In [72]:
                 predicted ratio=(ratios['Ratios'].values)[0]
           2
           3
                 error=[]
                 predicted values=[]
                 window size=3
           5
           6
                 predicted ratio values=[]
                 for i in range(0,4464*40):
           7
           8
                      if i%4464==0:
           9
                          predicted ratio values.append(0)
                          predicted values.append(0)
          10
          11
                          error.append(0)
          12
                          continue
                      predicted ratio values.append(predicted ratio)
          13
          14
                      predicted values.append(int(((ratios['Given'].values)[i])*predicted ratio))
                      error.append(abs((math.pow(int(((ratios['Given'].values)[i])*predicted ratio)-(ratios['Prediction']
          15
          16
                      if i+1>=window size:
                          predicted ratio=sum((ratios['Ratios'].values)[(i+1)-window size:(i+1)])/window size
          17
                      else:
          18
          19
                          predicted_ratio=sum((ratios['Ratios'].values)[0:(i+1)])/(i+1)
          20
          21
          22
                 ratios['MA R Predicted'] = predicted values
          23
                 ratios['MA R Error'] = error
          24
                 mape err = (sum(error))/len(error))/(sum(ratios['Prediction'].values))/len(ratios['Prediction'].values))
                 mse_err = sum([e**2 for e in error])/len(error)
          25
          26
                 return ratios, mape err, mse err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 3 is optimal for getting the best results using Moving Averages using previous Ratio values therefore we get $R_t = (R_{t-1} + R_{t-2} + R_{t-3})/3$

Next we use the Moving averages of the 2016 values itself to predict the future value using $P_t = (P_{t-1} + P_{t-2} + P_{t-3} \dots P_{t-n})/n$

```
def MA P Predictions(ratios, month):

          19
                 return ratios, mape err, mse err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 1 is optimal for getting the best results using Moving Averages using previous 2016 values therefore we get $P_t = P_{t-1}$

Weighted Moving Averages

The Moving Avergaes Model used gave equal importance to all the values in the window used, but we know intuitively that the future is more likely to be similar to the latest values and less similar to the older values. Weighted Averages converts this analogy into a mathematical relationship giving the highest weight while computing the averages to the latest previous value and decreasing weights to the subsequent older ones

Weighted Moving Averages using Ratio Values - $R_t = (N*R_{t-1} + (N-1)*R_{t-2} + (N-2)*R_{t-3}....1*R_{t-n})/(N*(N+1)/2)$

```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 2 is optimal for getting the best results using Weighted Moving Averages using previous 2016 values therefore we get $P_t = (2 * P_{t-1} + P_{t-2})/3$

Exponential Weighted Moving Averages

https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average

(https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average) Through weighted averaged we have satisfied the analogy of giving higher weights to the latest value and decreasing weights to the subsequent ones but we still do not know which is the correct weighting scheme as there are infinetly many possibilities in which we can assign weights in a non-increasing order and tune the hyperparameter window-size. To simplify this process we use Exponential Moving Averages which is a more logical way towards assigning weights and at the same time also using an optimal window-size.

In exponential moving averages we use a single hyperparameter alpha (α) which is a value between 0 & 1 and based on the value of the hyperparameter alpha the weights and the window sizes are configured.

For eg. If $\alpha=0.9$ then the number of days on which the value of the current iteration is based is~ $1/(1-\alpha)=10$ i.e. we consider values 10 days prior before we predict the value for the current iteration. Also the weights are assigned using 2/(N+1)=0.18, where N = number of prior values being considered, hence from this it is implied that the first or latest value is assigned a weight of 0.18 which keeps exponentially decreasing for the subsequent values.

$$R'_{t} = \alpha * R_{t-1} + (1 - \alpha) * R'_{t-1}$$

```

Comparison between baseline models

We have chosen our error metric for comparison between models as **MAPE** (**Mean Absolute Percentage Error**) so that we can know that on an average how good is our model with predictions and **MSE** (**Mean Squared Error**) is also used so that we have a clearer understanding as to how well our forecasting model performs with outliers so that we make sure that there is not much of a error margin between our prediction and the actual value

```
Error Metric Matrix (Forecasting Methods) - MAPE & MSE

Moving Averages (Ratios) - MAPE: 0.1821155173392136 MSE: 400.062550403225

Moving Averages (2016 Values) - MAPE: 0.14292849686975506 MSE: 174.8490199372

Weighted Moving Averages (Ratios) - MAPE: 0.1784869254376018 MSE: 384.015787410394

Weighted Moving Averages (2016 Values) - MAPE: 0.13551088436182082 MSE: 162.46707549283

Exponential Moving Averages (Ratios) - MAPE: 0.17783550194861494 MSE: 378.34610215053766

Exponential Moving Averages (2016 Values) - MAPE: 0.1350915263669572 MSE: 159.73614471326164
```

Plese Note:- The above comparisons are made using Jan 2015 and Jan 2016 only

From the above matrix it is inferred that the best forecasting model for our prediction would be:- $P_t^{'} = \alpha * P_{t-1} + (1-\alpha) * P_{t-1}^{'}$ i.e Exponential Moving Averages using 2016 Values

Regression Models

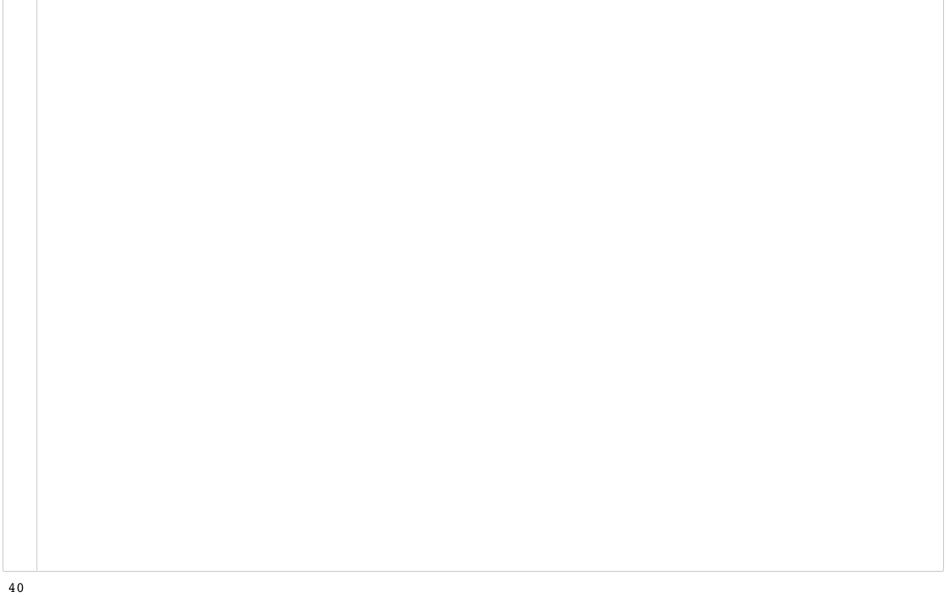

Train-Test Split

Before we start predictions using the tree based regression models we take 3 months of 2016 pickup data and split it such that for every region we have 70% data in train and 30% in test, ordered date-wise for every region

Fourier Features:
